

1. Structure of Result Section (Springer Standard)

Use this exact hierarchy:

4. Experimental Results and Performance Evaluation

- 4.1 Experimental Setup
- 4.2 Qualitative Results
- 4.3 Quantitative Evaluation
- 4.4 Robustness Analysis
- 4.5 Security and Steganalysis Resistance
- 4.6 Ablation Study
- 4.7 Comparative Analysis
- 4.8 Statistical Validation

2. Experimental Setup (Must Be Precise)

Include: Figure for all image including secret

Dataset

1. USC-SIPI / BOSSBase / ImageNet subset/Div2K(Any One)
2. Number of images (e.g., 20 images)

Parameters

1. Hash size (e.g., 64-bit perceptual hash)
2. LLM used (e.g., GPT-based / open-source LLM)
3. Token length

Evaluation Metrics (very important)

Since your method is coverless, DO NOT rely only on PSNR/SSIM.

Use:

- **Payload Capacity (bits/image or bits/sequence)**
- **Semantic Reconstruction Accuracy (%)**
- **Hash Matching Accuracy**
- **Bit Error Rate (BER)**
- **Retrieval Precision/Recall**
- **Time Complexity**

3. Qualitative Results (Visual Proof)

Include figures:

Figure Set 1:

- Original message → Generated image sequence

Figure Set 2:

- Image sequence → Reconstructed message

Figure Set 3:

- Failure cases (very important for reviewers)

Caption example:

Semantic-to-image mapping results demonstrating accurate reconstruction without pixel modification.

4. Quantitative Results (Core Acceptance Factor)

Create clear tables like:

Table : Reconstruction Accuracy

Message Length	Accuracy (%)	BER
Short (50 words)		
Medium		
Long		

Table : Payload Capacity Comparison

Method	Capacity	Distortion
LSB		
DCT		
Proposed LG-CISH		

Table : Computational Time

Stage	Time (ms)
LLM Encoding	
Hash Matching	

5. Robustness Analysis (Highly Critical)

Test against:

- Image compression (JPEG 50%, 70%)
- Noise (Gaussian, Salt & Pepper)
- Cropping / resizing

Table: Robustness Results

Attack	Accuracy (%)
JPEG 50%	

Noise	
Etc.	

This is crucial because your method relies on hash stability.

6. Security & Steganalysis Resistance

Since your method is coverless, emphasize:

Include:

1. CNN-based steganalysis (SRNet, XuNet)
2. Show detection accuracy $\approx$ random ($\approx 50\%$)

Table :

Method	Detection Accuracy
LSB	
DCT	
Proposed	

This is for a strong acceptance booster

7. Ablation Study (Very Important for Novelty)

Remove components and show effect:

Variant	Accuracy
Without LLM	
Without hashing	
Full model	

Shows each component is necessary.

8. Comparative Analysis (Mandatory)

Compare with:

1. LSB
2. DWT-DCT
3. Coverless steganography papers
4. Deep learning-based methods

Use Graphs:

1. Accuracy vs Payload
2. Robustness vs Attack strength

9. Statistical Validation (Often we Miss → Causes of Rejection)

Include:

- Mean $\pm$ Standard Deviation
- t-test or ANOVA

Example:

The proposed method shows statistically significant improvement ($p < 0.05$) over existing approaches.

10. Key Acceptance Boosters (DO NOT MISS)

1. Include at least 6–8 tables
2. Include clear graphs (not cluttered)
3. Provide failure analysis
4. Use recent baselines (2023–2025)
5. Show real-world applicability

Final Critical Insight

Your algorithm is non-traditional (coverless + LLM-based), so reviewers will question:

1. Reliability
2. Reproducibility
3. Practicality

Your results must *prove*:

1. It works consistently
2. It is robust
3. It is secure
